Commutator, a new component for management of peri-implant-bone defects. The objective of the study was to describe and compare the use of an innovative prototype (Commutator, Dentaaurum, Ispringen, Germany) and a conventional minimally invasive system (Accord, Dentaaurum) for surgically guided bone regeneration and implant placement in peri-implant-bone defects in the mandible and the maxilla. A prospective split-mouth randomized clinical trial was performed in which 50 patients were treated with either the prototype or the conventional step-cut flapless surgical technique for peri-implant-bone augmentation (n = 25 for each site). A total of 122 implants were placed into the mandible or the maxilla, respectively. A clinical and radiographic evaluation was performed at baseline and 12 months after surgery. The residual bone height on the implant-placed side was between 1.0 and 3.7 mm for the prototype, while the conventional site showed mean bone losses of 1.3 mm. No major complications were observed in either group. The prototype showed a significantly higher initial crestal healing score than the conventional technique for both the mandible (2.17 ± 0.21 and 1.68 ± 0.16 , $P = .013$) and the maxilla (2.25 ± 0.24 and 1.62 ± 0.23 , $P = .021$). At 1-year follow-up, 87 implants were successfully integrated in the test group and 81 implants in the control group ($P = .252$). In conclusion, this innovative intervention reduces the conventional surgical trauma in peri-implant-bone defects and leads to a significant increase in initial crestal bone levels.
