An application that allows webpages to easily display data from XML, XSD or XDR documents. Core XML Services consists of an XML parser, an XPath processor, and a set of classes that can be used in VBScript or JavaScript. What you should know A new XML-based structure has replaced the once-popular XHTML, with HTML being its main progenitor. The new type of structure is called Extensible Markup Language (XML) and is supported by Microsoft Core XML Services (MSXML), which is used for accessing, validating and manipulating XML data. XML is a language used to share data. There are two versions of XML: Simple XML (XML 1.0), which is also known as SGML (Standard Generalized Markup Language), and Extensible Markup Language (XML), which is an evolution of SGML. XML is very similar to HTML. Both languages are used to define tags, which are used to define the structure of a document. For instance, tags such as  and  define images. XML is one of the most popular technologies on the internet. Some software companies use it to describe their products and services, although this is not a requirement. Core XML Services also contains an XML parser, a processor that translates documents between XML, XML-Schema (XSD) and XDR (XDR - XML Data Representation). This means that you can get all your data in one source and only change your program. The reason for the existence of XML is that there is a need to have a common language to exchange data. As XML is XML, you cannot use it to save your data on a website or a hard disk. It has to be transferred by the web server. There are a lot of ways to save your data in XML format. The way that MS Core XML Services saves it in XML format is to use XML. You can then load that data into Core XML Services and use the classes to access it. For more information about Microsoft XML Services, please visit: [What you should know: MSXML is now Microsoft Core XML Services \(MSXML\)](#), and will be referred to as Core XML Services throughout this course. Core XML Services is a set of components that implement the possibility to process XSLT (Extensible Stylesheet Language Transformation) instructions in an XML format. Put differently, it plays a major role in allowing code written in VBScript or JavaScript to be used in XML-based applications, with support for various popular XML technologies such as XSD and XDR. Available components The elements that make all this possible are an API, an XML parser and an XPath processor, which can be used wisely to output the desired result. These components are interconnected and cannot function without each other; the XML
